## Limiting Reagent Examples from Lecture of 9/30/05

An efficient method for identifying the limiting reagent uses the idea that reactants combine in what might be called "sets" of moles indicated by the stoichiometric coefficients in the balanced equation. If we divide the moles of each reagent by its stoichiometric coefficient, the result with the lowest number will indicate the reagent with the fewest "sets", which is the limiting reagent. We then use the number of moles of this species (not its number of "sets") in all subsequent stoichiometric calculations. The following example illustrates this method.

Example: What is the theoretical yield of the reaction

$$
3 \mathrm{Ca}(\mathrm{OH})_{2}(s)+2 \mathrm{H}_{3} \mathrm{PO}_{4}(l) 6 \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{~s})+3 \mathrm{H}_{2} \mathrm{O}(l)
$$

when $10.00 \mathrm{~g} \mathrm{Ca}(\mathrm{OH})_{2}$ and $10.00 \mathrm{~g} \mathrm{H}_{3} \mathrm{PO}_{4}$ are mixed? [f.w. $\mathrm{Ca}(\mathrm{OH})_{2}=74.10 \mathrm{u}$; m.w. $\mathrm{H}_{3} \mathrm{PO}_{4}=$ 97.99 u; f.w. $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}=310.18$ u]
$\mathrm{mol} \mathrm{Ca}(\mathrm{OH})_{2}=\left(10.00 \mathrm{~g} \mathrm{Ca}(\mathrm{OH})_{2}\right)\left(1 \mathrm{~mol} \mathrm{Ca}(\mathrm{OH})_{2} / 74.10 \mathrm{~g} \mathrm{Ca}(\mathrm{OH})_{2}\right)=0.1349_{53} \mathrm{~mol} \mathrm{Ca}(\mathrm{OH})_{2}$
$\mathrm{mol} \mathrm{H}_{3} \mathrm{PO}_{4}=\left(10.00 \mathrm{~g} \mathrm{H}_{3} \mathrm{PO}_{4}\right)\left(1 \mathrm{~mol} \mathrm{H}_{3} \mathrm{PO}_{4} / 97.99 \mathrm{~g} \mathrm{H}_{3} \mathrm{PO}_{4}\right)=0.1020_{51} \mathrm{~mol} \mathrm{H}_{3} \mathrm{PO}_{4}$
To identify the limiting reagent divide each number of moles by its stoichiometric coefficient in the balanced equation, thereby determining the number of "sets" of each.

$$
\begin{gathered}
\text { "sets" } \mathrm{Ca}(\mathrm{OH})_{2}=\left(0.1349_{53} \mathrm{~mol} \mathrm{Ca}(\mathrm{OH})_{2}\right)\left(1 \text { "set" } \mathrm{Ca}(\mathrm{OH})_{2} / 3 \mathrm{~mol} \mathrm{Ca}(\mathrm{OH})_{2}\right) \\
=0.04498 \text { "set" Ca(OH})_{2}
\end{gathered}
$$

$$
\begin{gathered}
\text { "sets" } \mathrm{H}_{3} \mathrm{PO}_{4}=\left(0.1020_{51} \mathrm{~mol} \mathrm{H}_{3} \mathrm{PO}_{4}\right)\left(1 \text { "set" } \mathrm{H}_{3} \mathrm{PO}_{4} / 2 \mathrm{~mol} \mathrm{H}_{3} \mathrm{PO}_{4}\right) \\
=0.05103 \text { "set" } \mathrm{H}_{3} \mathrm{PO}_{4}
\end{gathered}
$$

## $\Rightarrow \mathrm{Ca}(\mathrm{OH})_{2}$ limits, because it has the fewer "sets".

Now, use the moles of $\mathrm{Ca}(\mathrm{OH})_{2}$ (not the number of "sets"!) in all subsequent calculations.

$$
\begin{gathered}
\mathrm{g} \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}=\left(0.1349_{53} \mathrm{~mol} \mathrm{Ca}(\mathrm{OH})_{2}\right)\left(1 \mathrm{~mol} \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2} / 3 \mathrm{~mol} \mathrm{Ca}(\mathrm{OH})_{2}\right) \\
=13.95 \mathrm{~g} \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}
\end{gathered}
$$

How many grams of $\mathrm{H}_{3} \mathrm{PO}_{4}$ are left over? Calculate the moles $\mathrm{H}_{3} \mathrm{PO}_{4}$ used, subtract this from the moles $\mathrm{H}_{3} \mathrm{PO}_{4}$ present, and convert the remaining number of moles to grams.
$\mathrm{mol} \mathrm{H}_{3} \mathrm{PO}_{4}$ used $=\left(0.1349_{53} \mathrm{~mol} \mathrm{Ca}(\mathrm{OH})_{2}\right)\left(2 \mathrm{~mol} \mathrm{H}_{3} \mathrm{PO}_{4} / 3 \mathrm{~mol} \mathrm{Ca}(\mathrm{OH})_{2}\right)=0.08996_{87} \mathrm{~mol} \mathrm{H}_{3} \mathrm{PO}_{4}$
$\mathrm{mol} \mathrm{H}_{3} \mathrm{PO}_{4}$ left $=\mathrm{mol}$ initial -mol used $=0.1020_{51} \mathrm{~mol}-0.08996_{87} \mathrm{~mol}=0.0121 \mathrm{~mol} \mathrm{H}_{3} \mathrm{PO}_{4}$
$\mathrm{g} \mathrm{H}_{3} \mathrm{PO}_{4}$ left $=\left(0.0121 \mathrm{~mol} \mathrm{H}_{3} \mathrm{PO}_{4}\right)\left(97.99 \mathrm{~g} \mathrm{H}_{3} \mathrm{PO}_{4} / \mathrm{mol} \mathrm{H}_{3} \mathrm{PO}_{4}\right)=1.18 \mathrm{~g} \mathrm{H}_{3} \mathrm{PO}_{4}$

Example: Iodic acid, $\mathrm{HIO}_{3}$, can be prepared by the following reaction

$$
\mathrm{I}_{2}(s)+5 \mathrm{H}_{2} \mathrm{O}_{2}(l) 62 \mathrm{HIO}_{3}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

What is the theoretical yield in grams of iodic acid in the reaction of $16.00 \mathrm{~g} \mathrm{I}_{2}$ and 10.00 g $\mathrm{H}_{2} \mathrm{O}_{2}$ ? How many grams of the non-limiting reagent will be left over? [Molecular weights: $\mathrm{I}_{2}=$ $\left.253.8 \mathrm{u}, \mathrm{H}_{2} \mathrm{O}_{2}=34.01 \mathrm{u}, \mathrm{HIO}_{3}=175.9 \mathrm{u}\right]$

First calculate the moles of each reactant, then divide each by its stoichiometric coefficient..

$$
\begin{aligned}
& \mathrm{mol} \mathrm{I}_{2}=\left(16.00 \mathrm{~g} \mathrm{I}_{2}\right)\left(1 \mathrm{~mol} \mathrm{I}_{2} / 253.8 \mathrm{~g} \mathrm{I}_{2}\right)=0.06304 \mathrm{~mol} \mathrm{I}_{2} \\
& \text { "sets" } \mathrm{I}_{2}=\left(0.06304 \mathrm{~mol} \mathrm{I}_{2}\right)\left(\text { "set" } \mathrm{I}_{2} / 1 \mathrm{~mol} \mathrm{I}_{2}\right)=0.06304 \text { "set" } \mathrm{I}_{2} \\
& \mathrm{~mol} \mathrm{H} \mathrm{H}_{2}=\left(10.00 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}_{2}\right)\left(1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2} / 34.01 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}_{2}\right)=0.2940 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2} \\
& \text { "sets" } \left.\mathrm{H}_{2} \mathrm{O}_{2}=\left(0.2940 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2}\right) \text { ("set } \mathrm{H}_{2} \mathrm{O}_{2} / 5 \mathrm{~mol} \mathrm{H} \mathrm{H}_{2}\right)=0.05880 \text { "set" } \mathrm{H}_{2} \mathrm{O}_{2}
\end{aligned}
$$

Therefore, moles of $\mathrm{H}_{2} \mathrm{O}_{2}$ limits and we will base our calculation of grams of $\mathrm{HIO}_{3}$ on it, not the moles of $\mathrm{I}_{2}$.

$$
\mathrm{g} \mathrm{HIO}_{3}{ }^{\prime}\left(0.2940 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2}\right)\left(\frac{2 \mathrm{~mol} \mathrm{HIO}_{3}}{5 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2}}\right)\left(\frac{175.9 \mathrm{~g} \mathrm{HIO}_{3}}{\mathrm{~mol} \mathrm{HIO}_{3}}\right){ }^{\prime} 20.69 \mathrm{~g} \mathrm{HIO}_{3}
$$

The $I_{2}$ is present in excess, so some of it will be left over after the reaction is complete. As in the preceding example, calculate how many moles of $I_{2}$ is used, subtract from the moles initially present, and convert the remaining number of moles to grams.

$$
\begin{aligned}
& \mathrm{mol} \mathrm{I}_{2} \text { used }=\left(0.2940 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2}\right)\left(1 \mathrm{~mol}_{2} / 5 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2}\right)=0.05880 \mathrm{~mol} \mathrm{I}_{2} \\
& \mathrm{~mol} \mathrm{I}_{2} \text { left }=\mathrm{mol} \text { initial }-\mathrm{mol} \text { used }=0.06304 \mathrm{~mol}-0.05880 \mathrm{~mol}=0.00424 \mathrm{~mol} \mathrm{I}_{2} \\
& \mathrm{~g} \mathrm{I}_{2} \text { left }=\left(0.00424 \mathrm{~mol} \mathrm{I}_{2}\right)\left(253.8 \mathrm{~g} \mathrm{I}_{2} / \mathrm{mol} \mathrm{I}_{2}\right)=1.07_{61} \mathrm{~g} \mathrm{I}_{2}=1.08 \mathrm{I}_{2}
\end{aligned}
$$
